```

Comments on Time and Slope

```
%TIME:
%All three methods are pretty quick, however the Newton and Halley methods
%are not only faster but much much more accurate. Theoretically halleys
%method should be faster than newtons method but probably because of the
%way I programmed each function or the brackets that I gave each function.
%But the halley and newton method are incredibly similar.
```

```
%SLOPE:
%Firstly the function semilogy() turns the y axis into a logarithmic scale
%while leaving the x axis alone. From this scale you can visually see how
%the slopes of Newtons and Halleys method are much steeper than that of the
%bisection. This is because the bisection method will close in linearly
%through its method of finding a midpoint every iteration, which is slow
%compared to Newtons and Halleys method where they use derivatives to point
%to the root and converge much quicker. The steeper a negative slope is the
%faster that method converges.
```

Halley's Method Function

```
%Halley Pseudocode:
%almost the same as newtons method except now also use the 2nd derivative,
%it iterates until it reaches desired tolerance. It uses the derivatives to
%find roots by following the slope
```

```
function [M1,error,it] = halley(d, M, fx, gx, hx, tol)
    M1 = zeros(d,2); % stores the roots found
    for n = 1:d
        a = M(n,1); % defines where to place the roots
        b = M(n,2);
        xo = (a+b)/2;
        xoo = 0;
```

```

count = 0;
x0 = 0;
while abs(fx(x0))>tol %check tol
    x0 = x0; %reset for iteration
    x0 = x0 - (2*fx(x0)*gx(x0))/(2*gx(x0)^2 - fx(x0)*hx(x0));
%formula
    x0 = x0;
    count = count + 1;
    if n == 1
        error(count,1) = count;
        error(count,2) = x0;
        it(count,1) = count;
    end
end
M1(n) = x0; %save roots
M1(n,2) = fx(x0);
end
end

```

Newton's Method Function

%Newtons psuedocode:
 %Use previous brackets to find general locations of all roots, then use
 %derivative to follow slope to x-axis and close in on root until the
 %tolerance is met.

```

function [M1,error,it] = newton(d, M, fx, gx, tol)
    M1 = zeros(d,2); % stores the roots found
    for n = 1:d
        a = M(n,1); %finding roots
        b = M(n,2);
        x0 = (a+b)/2;
        x00 = 0;
        count = 0;
        x0 = 0;
        while abs(fx(x00))>tol %checking tol
            x00 = x0; %reset for iteration
            x0 = x0 - fx(x0)/gx(x0); %Formula
            x0 = x0;
            count = count + 1;
            if n == 1
                error(count,1) = count;
                error(count,2) = x0;
                it(count,1) = count;
            end
        end
        M1(n) = x0; %save roots
        M1(n,2) = fx(x0);
    end
end
end

```

Bisection Function

%Bisection Pseudocode:

%Step in big steps like the bracketing except when it finds a big step with
%a root it then starts closing in by finding out which side the root is
%closer to and then setting the respective endpoint to the midpoint and
%then restarts until the root is found at desired tolerance.

```
